Overview

Carbon dioxide, aka CO₂, is a gas that is an essential part of the Earth's atmosphere and life in general. However, while essential, it can have negative effects when concentrations exceed certain level. It can impact the entire planet via global warming. But it can also have very local effects, for example on indoor air quality. Elevated levels of CO₂ can lead to reduced cognitive ability and other health related concerns. Therefore, monitoring CO₂ levels of inside air can be useful as a part of gauging general air quality.

Numerous projects have already been done to monitor indoor CO₂. This project posted to Hackster uses an ESP8266 and a CCS811 to send values to Adafruit IO. This tweet (and also bl
og post (https://adafru.it/Qek) with more info) shares a project done by an 11 year old and is based on the Feather ecosystem using the SCD-30 (https://adafru.it/QfK) CO₂ sensor from Sensirion. This is an excellent true CO₂ concentration sensor which we also use in this project.

In this project we use the SCD-30 along with a Matrix Portal to drive a 64x32 RGB LED matrix. This provides a nice way to display the current conditions and have it be readable to an entire room. And as a bonus, with this hardware arrangement, there is no soldering required!

This project does NOT require any soldering and the matrix is really big so its visible in a classroom, workshop, or on the wall of a home!

Hardware

Here's a summary of the hardware needed for this project. Some items are optional. Also note that if you purchased an Adabox 016 (https://adafru.it/ODd), you will have most of these items already.

The key item is of course the SCD-30 CO2 sensor itself:

Adafruit SCD-30 - NDIR CO2 Temperature and Humidity Sensor
Take a deep breath in...now slowly breathe out. Mmm isn't it wonderful? All that air around us, which we bring into our lungs, extracts oxygen from and then breathes out carbon...
https://www.adafruit.com/product/4867

To provide a solderless way to connect the SCD-30 to the Matrix Portal, you can use a STEMMA QT cable. They come in various lengths:
STEMMA QT / Qwiic JST SH 4-Pin Cable
This 4-wire cable is 50mm / 1.9" long and fitted with JST SH female 4-pin connectors on both ends. Compared with the chunkier JST PH these are 1mm pitch instead of 2mm, but...
https://www.adafruit.com/product/4399

STEMMA QT / Qwiic JST SH 4-Pin Cable - 100mm Long
This 4-wire cable is a little over 100mm / 4" long and fitted with JST-SH female 4-pin connectors on both ends. Compared with the chunkier JST-PH these are 1mm pitch instead of...
https://www.adafruit.com/product/4210

STEMMA QT / Qwiic JST SH 4-Pin Cable - 200mm Long
This 4-wire cable is a little over 200mm / 7.8" long and fitted with JST-SH female 4-pin connectors on both ends. Compared with the chunkier JST-PH these are 1mm pitch instead of...
https://www.adafruit.com/product/4401

You'll also need a 64x32 LED matrix and a Matrix Portal to drive the matrix:
Adafruit Matrix Portal - CircuitPython
Powered Internet Display

https://www.adafruit.com/product/4749

CO2 Air Levels
The SCD-30 sensor reports the CO₂ levels in units of parts per million (https://adafru.it/QfL) (ppm). This is a bit of a wacky unit of measure, but is pretty much what it
says. If you had a million "parts" of air, then how many "parts" of CO₂ does it contain. Or as OSHA (https://adafruit.it/QfM) defines it:

Parts of vapor or gas per million parts of contaminated air by volume at 25 °C and 760 torr.

From the SCD-30 datasheet (https://adafruit.it/QfN) we can see that the sensor range is 400 to 10000 ppm:

But how do these ppm levels translate into air quality? Below is a PDF that covers lots of issues related to indoor air quality:

Buried in Appendix A is a section that discusses carbon dioxide levels. The key one they mention is the 5000 ppm Permissible Exposure Limit (PEL). Think of that as the upper limit - your workplace should ideally be below that level.

Values below the 5000 ppm PEL limit are commonly broken down into these subjective ranges, which we have also adopted for use in this project.

- < 1000 = Good air. Your body will be happy!
- 1000 - 2000 = Poor air. See if there is any way to improve.
- 2000 - 5000 = Warning levels. Good idea to investigate why.
- > 5000 = Dang, you are above the OSHA Permissible Exposure Limit for 8 hour exposure. Something should be done.
So by "Dang" do you mean "Dangerous"? Sort of, but not like immediately dangerous. That requires levels greater than around 15,000 ppm (see PDF linked above). So it's not like you need to run for your life if the ppm jumps above 5000. But you don't want to spend extended periods of time in that environment.

Matrix Display of Air Quality

The general idea for the Matrix Portal based air quality display is pretty simple. It has a readout of the current CO₂ levels in ppm so that value it always viewable. Then, for each of the four ranges above, there is an associated "smiley face" icon and word. This combination of icon/word was chosen as way to make the display more universally readable. The smileys don't rely on any specific language and additionally use color to help reinforce the condition. The green=good and red=bad association is fairly universal. But not everyone can distinguish the red/green colors. So the word provides an additional textual (but in English only) indication in a single color.

Hopefully with the combination of the two, smiley + word, the message is universally understood.

CO₂ ppm < 1000

1000 ≤ CO₂ ppm < 2000
2000 <= CO2 ppm < 5000

CO2 ppm >= 5000
Prep the MatrixPortal

Power Prep
The MatrixPortal supplies power to the matrix display panel via two standoffs. These come with protective tape applied (part of our manufacturing process) which MUST BE REMOVED!

Use some tweezers or a fingernail to remove the two amber circles.
Power Terminals
Next, screw in the spade connectors to the corresponding standoff.

- red wire goes to +5V
- black wire goes to GND

Panel Power
Plug either one of the four-conductor power plugs into the power connector pins on the panel. The plug can only go in one way, and that way is marked on the board's silkscreen.
Board Connection

Now, plug the board into the left side shrouded 8x2 connector as shown. The orientation matters, so take a moment to confirm that the white indicator arrow on the matrix panel is oriented pointing up and right as seen here and the MatrixPortal overhangs the edge of the panel when connected. This allows you to use the edge buttons from the front side.

Check nothing is impeding the board from plugging in firmly. If there's a plastic nub on the matrix that's keeping the Portal from sitting flat, cut it off with diagonal cutters.
Install CircuitPython

CircuitPython (https://adafru.it/tB7) is a derivative of MicroPython (https://adafru.it/BeZ) designed to simplify experimentation and education on low-cost microcontrollers. It makes it easier than ever to get prototyping by requiring no upfront desktop software downloads. Simply copy and edit files on the CIRCUITPY drive to iterate.

Set up CircuitPython Quick Start!

Follow this quick step-by-step for super-fast Python power :)

Download the latest version of CircuitPython for this board via circuitpython.org

https://adafru.it/Nte

Further Information

For more detailed info on installing CircuitPython, check out Installing CircuitPython (https://adafru.it/Amd).
Click the link above and download the latest UF2 file.

Download and save it to your desktop (or wherever is handy).

Plug your MatrixPortal M4 into your computer using a known-good USB cable.

A lot of people end up using charge-only USB cables and it is very frustrating! So make sure you have a USB cable you know is good for data sync.

Double-click the Reset button (indicated by the green arrow) on your board, and you will see the NeoPixel RGB LED (indicated by the magenta arrow) turn green. If it turns red, check the USB cable, try another USB port, etc.

If double-clicking doesn't work the first time, try again. Sometimes it can take a few tries to get the rhythm right!
You will see a new disk drive appear called MATRIXBOOT.

Drag the adafruit_circuitpython_etc.uf2 file to MATRIXBOOT.

The LED will flash. Then, the MATRIXBOOT drive will disappear and a new disk drive called CIRCUITPY will appear.

That's it, you're done! :)

---

CircuitPython Setup

To use all the amazing features of your MatrixPortal M4 with CircuitPython, you must first install a number of libraries. This page covers that process.
Adafruit CircuitPython Bundle

Download the Adafruit CircuitPython Library Bundle. You can find the latest release here:

![Download latest Library Bundle](https://adafruit.it/ENC)

Download the adafruit-circuitpython-bundle-version-mpy-*.zip bundle zip file, and unzip a folder of the same name. Inside you'll find a lib folder. The entire collection of libraries is too large to fit on the CIRCUITPY drive. Instead, add each library as you need it, this will reduce the space usage but you'll need to put in a little more effort.

At a minimum we recommend the following libraries, in fact we more than recommend. They're basically required. So grab them and install them into CIRCUITPY/lib now!

- adafruit_matrixportal - this library is the main library used with the MatrixPortal.
- adafruit_portalbase - This is the base library that adafruit_matrixportal is built on top of.
- adafruit_esp32spi - this is the library that gives you internet access via the ESP32 using (you guessed it!) SPI transport. You need this for anything Internet
- neopixel.mpy - for controlling the onboard neopixel
- adafruit_bus_device - low level support for I2C/SPI
- adafruit_requests.mpy - this library allows us to perform HTTP requests and get responses back from servers. GET/POST/PUT/PATCH - they're all in here!
- adafruit_fakerequests.mpy - This library allows you to create fake HTTP requests by using local files.
- adafruit_io - this library helps connect the PyPortal to our free data logging and viewing service
- adafruit_bitmap_font - we have fancy font support, and it's easy to make new fonts. This library reads and parses font files.
- adafruit_display_text - not surprisingly, it displays text on the screen
- adafruit_lis3dh.mpy - this library is used for the onboard accelerometer to detect the orientation of the MatrixPortal
Code

Here's how to load the code and assets as well as some additional libraries you'll need.

Additional Libraries

In addition to the libraries mentioned in the main Matrix Portal prep section under CircuitPython Setup, make sure you also have these project specific libraries installed in your CIRCUITPY/lib folder.

You can download the latest library bundle from the [CircuitPython webpage](https://adafruit.it/ENC).

- adafruit_imageload - Used to load the BMP files. Be sure to copy the entire folder.
- adafruit_scd30.mpy - The driver for the SCD-30 CO₂ sensor.

Here's a summary of what your CIRCUITPY/lib folder should end up looking like:
Here's the code for the Matrix Portal CO₂ Monitor. Use the Project Zip link to download the code as well as the bitmaps files used in a single zip file.

Drag the entire bmps folder to your CIRCUITPY folder. That creates a subfolder that will contain the BMPs.

Save the code listing as code.py into your CIRCUITPY folder so it will run automatically when powered up.

```python
import time
import board
import displayio
import adafruit_imageload
from adafruit_matrixportal.matrix import Matrix
import adafruit_scd30

# --| User Config |----
CO2_CUTOFFS = (1000, 2000, 5000)
UPDATE_RATE = 1
# ---------------------
```

©Adafruit Industries
# the sensor
scd30 = adafruit_scd30.SCD30(board.I2C())

# optional if known (pick one)
# scd30.ambient_pressure = 1013.25
# scd30.altitude = 0

# the display
matrix = Matrix(width=64, height=32, bit_depth=6)
display = matrix.display
display.rotation = 90  # matrixportal up
# display.rotation = 270  # matrixportal down

# current condition smiley face
smileys_bmp, smileys_pal = adafruit_imageload.load("/bmps/smileys.bmp")
smiley = displayio.TileGrid(
    smileys_bmp,
    pixel_shader=smileys_pal,
    x=0,
    y=0,
    width=1,
    height=1,
    tile_width=32,
    tile_height=32,
)

# current condition label
tags_bmp, tags_pal = adafruit_imageload.load("/bmps/tags.bmp")
label = displayio.TileGrid(
    tags_bmp,
    pixel_shader=tags_pal,
    x=0,
    y=32,
    width=1,
    height=1,
    tile_width=32,
    tile_height=16,
)

# current CO2 value
digits_bmp, digits_pal = adafruit_imageload.load("/bmps/digits.bmp")
co2_value = displayio.TileGrid(
    digits_bmp,
    pixel_shader=digits_pal,
    x=0,
    y=51,
    width=4,
    height=1,
    tile_width=8,
    tile_height=10,
)

# put em all together
splash = displayio.Group()
splash.append(smiley)
splash.append(label)
splash.append(co2_value)

# and show em
display.show(splash)

def update_display(value):
    value = abs(round(value))
    # smiley and label
    if value < CO2_CUTOFFS[0]:
        smiley[0] = label[0] = 0
```python
elif value < CO2_CUTOFFS[1]:
    smiley[0] = label[0] = 1
elif value < CO2_CUTOFFS[2]:
    smiley[0] = label[0] = 2
else:
    smiley[0] = label[0] = 3

# CO2 value
# clear it
for i in range(4):
    co2_value[i] = 10
# update it
i = 3
while value:
    co2_value[i] = value % 10
    value = int(value / 10)
    i -= 1

while True:
    # protect against NaNs and Nones
    try:
        update_display(scd30.CO2)
    except:
        pass
time.sleep(UPDATE_RATE)
```

---

**CO2 Sensor Setup**

Connecting the SCD-30 sensor to the Matrix Portal is easy thanks to the [STEMMA QT connector system](https://adafruit.it/Ft4).

Pretty simple. Use the STEMMA QT cable to connect the SCD-30 to the Matrix Portal.

Where to actually place the SCD-30 is sort of up to you and your specific setup. However, you’ll want to put a little thought into it to make sure the sensor is properly exposed to the ambient air conditions. Sensirion actually has a document with some guidelines you can read below:

[SCD30 Sensor Placement Guidelines](https://adafruit.it/PFf)
For example, make sure the sensor isn't exposed to direct sunlight. They also have a nice diagram to illustrate suggested placement within an enclosure:

![Diagram showing correct and incorrect sensor placements.]

There's also information related to self heating and use in a moving air duct. So give that document a read to help determine where and how best to locate the SCD-30.

CircuitPython Usage

If you want more in depth coverage of using the SCD-30 sensor in CircuitPython, checkout the main guide for the sensor below:

[SCD-30 Python & CircuitPython](https://adafru.it/QfP)

What Font?

If you've done other CircuitPython projects involving text and displays, you've probably used a custom font file. That's a great way to get a nice custom look to project read outs. But you may have noticed - this project has no font file.

So how did we get those nice bold text readouts? Let's talk about that a bit. It's a trick that could be useful for other projects. We'll mainly focus on the way the CO₂ reading was done.

Sprite Sheet Instead of Font File

At the heart of the CircuitPython [displayio](https://adafru.it/EGh) library is the concept of [TileGrids](https://adafru.it/GC1). This lets you carve up a source bitmap into multiple sections (tiles) and then layout one or more of them (grid). You can do this with any bitmap, but here we use one that contains the numbers 0-9. It was created by hand in [GIMP](https://adafru.it/GCa):
The max value the SCD30 can report is 10000 ppm. Ignoring that upper limit, every other reading is at most 4 digits wide. The LED matrix we use is 32 pixels wide. Mathy McMathy says "32 / 4 = 8" so we make each digit be 8 pixels wide. We chose 10 pixels for the height as a "meh, that looks about right" value.

Loading the source Bitmap into our code is just one line of code:

```
digits_bmp, digits_pal = adafruit_imageload.load("/bmps/digits.bmp")
```

Setting up our TileGrid that will use this source Bitmap is also a single line of code, but there are numerous parameters that get used:

```
c02_value = displayio.TileGrid(
    digits_bmp,
    pixel_shader=digits_pal,
    x=0,
    y=51,
    width=4,
    height=1,
    tile_width=8,
    tile_height=10,
)
```

We tell it to use `digits_bmp`, and its associate color palette `digits_pal`, as our source Bitmap. We also go ahead and set our location on the matrix with `x` and `y`. Now for the more important ones to understand. With `width` and `height` we are setting the size of the resulting TileGrid in terms of number of tiles. The similarly named `tile_width` and `tile_height` are what actually set the individual tile size - and how the source bitmap is carved up. The result looks something like this:
The `co2_value` TileGrid is 4 x 1 tiles. Each of these tiles can "point" to any of the possible source tiles, 0 - 10, from the source Bitmap `digits_bmp`. The syntax for doing that would look like:

```python
c02_value[1] = 4
```

to set the second digit (index 1) to 4 as an example.

By creating our source bitmap with the digits arranged as they are, the indices correspond to the actual digits, 3=3, 7=7, etc. That lets us use the digits from the actual CO₂ reading to set each tile. That's what this bit of code does:

```python
# CO2 value
# clear it
for i in range(4):
    co2_value[i] = 10
# update it
i = 3
while value:
    co2_value[i] = value % 10
    value = int(value / 10)
    i -= 1
```

So it looks like we are printing text using a blocky font, but we are not. It's all done with a bitmap file. Pretty neat trick, huh?

**Why Do That?**

So why do this TileGrid / Bitmap file approach vs. just using a font file and formatted prints? Mainly for precise control of the resulting output. Like pixel-by-pixel control. The LED matrix is physically large but is pretty low resolution - only 64 x 32. And our CO₂ value readout uses only 8x10 pixel digits. Getting a font to render exactly like you want at that low of a resolution can sometimes be tricky. And since we only needed digits, not a full alphabet, we just felt we could get there quicker with this approach.

TileGrids can be a bit tricky to wrap your head around at first. Hopefully this example not only helps illustrate how they work, but also maybe a neat way you can use them in your projects. Be sure to checkout the [Displayio Learn Guide](https://adafruit.it/EGh) for more details.
Changing The Text Labels

The text readouts are done with the four English words GOOD, POOR, WARN, and DANG. This was also done using a TileGrid / Bitmap combo. Here's the source bitmap:

![Source bitmap for text labels]

It's simpler than the CO2 value read out. It's just a single tile which points to one of the 32x16 pixel words. If you wanted to change the text, you could do so by editing the source bitmap. Since it's a bitmap, you can make it be whatever you want. No need to find a font that supports a specific language.

Changing The Smileys

The smiley face icons also come from a source bitmap:

![Source bitmap for smiley icons]

So they could also be changed if you wanted by simply editing each of the sub 32x32 pixel icons.
3D Printed Sensor Case

We designed a 3D printed bracket for the display and sensor so the parts are nicely secured.

You can use a screw or nail to hang it on a wall with our 3D printed bracket.

The bracket is secured to the heat set inserts that are built into the frame of the display.

The sensor is press fitted into the case with openings on the side for the cables.

The cover snap fits over the case and features holes to allow air to reach the sensor.

The bracket and enclosure parts are 3d printed without any support material using PLA filament.

The Wall hanger is attached the Matrix with M3 screws.

Parts List

STL files for 3D printing are oriented to print "as-is" on FDM style machines. Parts are designed to 3D print without any support material. Original design source may be downloaded using the links below.
Medium Sized Matrix ([Adabox 16](https://adafruit.it/ODd))

- CO2-Lid-txt
- CO2-Case
- CO2-Bracket ([https://www.adafruit.com/product/2278](https://adafruit.it/LFP))
- CO2-Wall-Hang

Large Matrix PID: 2276 ([https://www.adafruit.com/product/2276](https://adafruit.it/QBU))

- CO2Bracket-LG
- CO2-Wall-Hang-LG.stl
- Wall-Hang-LG

**Edit Matrix CO2 Parts**
[https://adafruit.it/QBV](https://adafruit.it/QBV)

**Download STLs**
[https://adafruit.it/QCG](https://adafruit.it/QCG)

**Slicing Parts**

Slice with settings for PLA material. The parts were sliced using CURA using the slice settings below.

- PLA filament 215c extruder
- 0.2 layer height
- 10% gyroid infill
- 60mm/s print speed
- 60c heated bed
Case Assembly

The bracket is secured to the enclosure using M2.5 hardware screws and hex nuts.

The bracket is secured to the heat set inserts that are built into the frame of the display.

The sensor is press fitted into the case with openings on the side for the cables.

The cover snap fits over the case and features holes to allow air to reach the sensor.
