Overview

Vertical Clock

This simple vertical version on the ever-popular wordclock spells out the time by illuminating rows of words. Reading from top to bottom, any five minute increment of time can be spelled out by illuminating some combination of these rows. (Credit to Twitter user @3d0g [https://adafru.it/Fi9] for this concept.)

This project uses a laser engraved piece of acrylic paired with a cardboard stand and is lit by a strip of NeoPixels [https://adafru.it/dAR] powered by a Feather M4 Express [https://adafru.it/Cmy] board with a Precision Real Time Clock FeatherWing [https://adafru.it/wiD] keeping time even if the clock is disconnected from power.

Adafruit NeoPixel LED Side Light Strip - Black 60 LED

Materials

In addition to the electronics, for this project you will need:

- Scrap corrugated cardboard
- Scissors and/or box cutter
- Hot glue gun (https://adafruit.it/Djk)
- Hot glue sticks (https://adafruit.it/Dlg)
- Soldering iron

Read on to learn how to build your own!
Circuit Diagram

The circuit for this project requires a few soldered connections. Follow the diagram below to see how the circuit is constructed.

This circuit includes an optional switch that will allow the user to toggle the clock daylight savings time (+ one hour).

Start building this circuit by connecting the power and GND lines to the terminal blocks on the DC power adapter.
Solder Time
The Feather needs Female headers (https://adafru.it/waW) soldered on. Solder male headers (included with the 'Wing) onto the RTC FeatherWing.

Solder the jumper cables from the terminal block to the Feather M4 and Featherwing.

Plug RTC FeatherWing into Feather M4 Express.

Flexible Power Source
This circuit arrangement will allow you to conveniently power your clock via a micro USB cable or a 5V DC power supply interchangeably.

The small coin cell battery in the RTC FeatherWing will keep time for you even if the clock is unplugged, so you never have to worry about setting the time.
Daylight Savings Time

To account for the spring forward and fall back cycle we go through every 6 months, a small switch can be added to the circuit to allow the user to toggle the time forward an hour and back when needed.
Toggle Switch
Bend the legs of the slide switch 90 degrees.

Solder one wire from the middle leg of the switch to the GND line.

Connect the left leg of the switch to pin #6 on the RTC FeatherWing.

Now, flipping this switch to the left will activate Daylight Savings mode, adjusting the clock one hour forward.
CircuitPython

Getting familiar with CircuitPython

CircuitPython ([https://adafruit.it/CgS](https://adafruit.it/CgS)) is a programming language based on Python, one of the fastest growing programming languages in the world. It is specifically designed to simplify experimenting and learning to code on low-cost microcontroller boards.

CircuitPython is easiest to use within the Mu Editor. If you haven't previously used Mu, [this guide will get you started](https://adafruit.it/ANO).

Preparing your Board

1) Download the latest 4.0 library pack ([https://adafruit.it/zB-](https://adafruit.it/zB-)).

2) Unzip it the library pack and drag the `adafruit_bus_device`, `adafruit_ds3231`, `adafruit_register`, and `neopixel` libraries over into the `/lib` folder on CIRCUITPY.

If there is no `lib` directory on your CIRCUITPY drive, create one to put the file into.

More info on installing libraries can be found [here](https://adafruit.it/C9M).
Make sure you have the following libraries installed:

- adafruit_bus_device
- adafruit_ds3231
- adafruit_register
- neopixel

Setting the Time

First things first, let's tell the RTC FeatherWing what time it is!

Copy and paste the code below into Mu. In line 22, fill in the correct year, month, day, hour, and minute. Save this as code.py to your CIRCUITPY device.

(More details on using the DS3231 Precision RTC can be found in [this guide](https://adafru.it/Fia))
Once the time has been set we're ready to move on to uploading the Wordclock code.

Vertical Wordclock Code

Make sure you've connected the Feather M4 Express to your computer (mac/PC/Linux) via a known good USB A to micro-B cable. Your board should show up as a flash disk drive named CIRCUITPY (If you see a disk name FEATHERBOOT, try pressing the reset button again. If the only drive name you get is named FEATHERBOOT, CircuitPython may not be loaded on the board. You can load CircuitPython as per this guide (https://adafru.it/AFI)).

Once your board is connected, copy the code below from the window below to a file on the Feather CIRCUITPY drive as code.py. You can select Download in the upper left to save the code onto your computer.

```python
# Write the time for the Adafruit DS3231 real-time clock.
# Limor Fried/Mike Barela for Adafruit Industries

import time
import board
import busio as io
import digitalio
import adafruit_ds3231

i2c = io.I2C(board.SCL, board.SDA)

# Create the RTC instance:
rtc = adafruit_ds3231.DS3231(i2c)

LED13 = digitalio.DigitalInOut(board.D13)
LED13.direction = digitalio.Direction.OUTPUT

# pylint: disable-msg=bad-whitespace
# pylint: disable-msg=using-constant-test
if True:
    #                     year, mon, date, hour, min, sec, wday, yday, isdst
    t = time.struct_time((2019, 7, 10, 17, 0, 0, 0, -1, -1))
    # you must set year, mon, date, hour, min, sec and weekday
    # yearday is not supported
    # isdst can be set but we don't do anything with it at this time
    print("Setting time to: ", t)  # uncomment for debugging
    rtc.datetime = t
    print("Done!")
    LED13.value = True
# pylint: enable-msg=using-constant-test
# pylint: enable-msg=bad-whitespace

# Main loop
LEDstate = 0
Write_Now = True

while True:
    t = rtc.datetime
    # print("The date is {} {}//{}\).format(days[int(t.tm_wday)],
    # to use @feeds,\, please set @feed_key")
Open the code up in the Mu editor. Press the **Save** button and your code should automatically be saved to the **CIRCUITPY** disk drive (which appears when the Feather M4 Express is plugged into your computer) as **code.py**.

```python
# t.tm_mday, t.tm_mon, t.tm_year))
# print("The time is {}:{}:{:02}".format(t.tm_hour, t.tm_min, t.tm_sec))
hour = t.tm_hour
if not Slide_Switch.value:  # Slide switch activate = Daylight savings
    # print("Switch detected for daylight savings")
    if hour == 24:
        hour = 1
    else:
        hour += 1
Write_Now = True  # Trigger a write
minute = t.tm_min
second = t.tm_sec
if second == 59 or Write_Now:
    # print("The time is {}:{}").format(t.tm_hour, t.tm_min)
    pixels.fill((0, 0, 0))  # blank all pixels for change
    the_time = writetime(hour, minute)
    for i in range(0, 21):  # Check all bits
        if the_time & 1 << i:  # If the bit is true
            pixels[i+1] = COLOR  # set pixel on (shift up 2 for buried one)
    pixels.show()
if LEDstate == 0:  # Flash the D13 LED every other second for activity
    LED13.value = True
    LEDstate = 1
else:
    LED13.value = False
    LEDstate = 0
Write_Now = False
    time.sleep(1)  # wait a second
```

Make sure the file saved to **CIRCUITPY** is named "**code.py**", this will allow it to run automatically when your Feather is powered on.

**Making Changes**

If you'd like to adjust the color of your clock, this can be changed in **line 29** of the code. Simply change the numbers in **COLOR = (0, 200, 0)** (green) - make the clock glow blue (0, 0, 200) or red (200, 0, 0), or any color in between! A great color picker is at [https://www.w3schools.com/colors/colors_picker.asp](https://www.w3schools.com/colors/colors_picker.asp) ([https://adafruit.it/BPY](https://adafruit.it/BPY)).
Laser Cutting

The face of this clock is made from a piece of acrylic that's engraved and cut so as to contain the light from each NeoPixel so that each word glows distinctly.

This file has the words spaced to align with the spacing between each NeoPixel, 0.656" between centers. The words are engraved, the outlines cut.
Build the Clock

The frame for your clock can be as simple or as fancy as you wish. Here, a minimalist and inexpensive option is shown, creating a thin channel in which to hold the NeoPixel strip and a small cardboard base to keep it standing.

NeoPixel Channel
Cut three long, thin strips of cardboard.

Glue them together to create a channel that will hold the NeoPixel strip.

Lay the NeoPixel strip into the channel to test its fit.
Clock Foundation

Cut three rectangular sections of cardboard.
Make a small square hole through two of them and cut a longer channel out of the third.
Glue the three pieces together, putting the channel on the bottom
Be careful using hot glue as the dispenser and fresh glue can cause burns.
Bring it Together

Glue two strips of cardboard on the base to hold the bottom of the acrylic in place.

Use hot glue to affix the NeoPixel channel to the base, centering it over the hole cut for the strip.

Thread the NeoPixel strip through the hole in the base, pulling it all the way through so the last pixel is at the top of the channel. *Keep in mind the bottom pixel will be hidden in the base of the clock;* it is ignored in the code, this is ok.

Add two more strips of cardboard to the bottom of the base, pinning the end of the NeoPixel strip so that it comes out the back.
Add Acrylic
Slot acrylic piece into place.

As a final touch, once the acrylic piece is in place, add a dab of hot glue to the top to keep the acrylic held tightly against the NeoPixel strip.
Power on your clock and you should see the time pop up!
